Does λ stop growth by itself? With a price the candidate set decays geometrically; without one it grows

λ=0.002
λ=0.006
fraction of triangles with residual / bytes > λ
at each densification interval (500 steps, 1000–9500).
grey: λ ≤ 6e-4 per Mpx: the candidate set GROWS;
only the add_percentage limiter / 4M cap stops it.
green: λ ≥ 1.85e-3: after the opacity floor starts
(5000) the candidate set decays geometrically,
half-life ≈ 3000 steps at λ=6e-3 (4.5–7.6 intervals),
≈ 5000–10000 steps at λ=2e-3.
Triangle count 7500→9500: within ±8 % at λ=6e-3
on 7/7 scenes (growth ≈ pruning: a steady state set
by λ); at λ=2e-3 flat on 4/7, still +8…+24 % on
bicycle / counter / kitchen; λ=0: +48 %.
vertical lines: start_pruning 4000, opacity floor 5000.
